Note: Within nine months from the publication of the mention of the grant of the European patent, any person may give notice to the European Patent Office of opposition to the European patent granted. Notice of opposition shall be filed in a written reasoned statement. It shall not be deemed to have been filed until the opposition fee has been paid (Art. 99(1) European patent convention).

Description

This invention relates to a system for accessing a plurality of base stations by means of a remote unit or key, and particularly for controlling a function in at least one of the base stations.

It is known to open or unlock the door of a vehicle or perform another function by operation of a miniature remote unit or electronic key which is generally carried on the key chain of the vehicle operator. By pressing a button on the remote unit, a coded radio frequency signal is transmitted to a base unit on the vehicle and, if recognized as an authorized code, the base unit unlocks the door or performs another predetermined function. It is recognized that such systems are not limited to controlling vehicle functions and can be used to control garage doors, security gates, or home entry, for example.

Since it is common practice for an operator to use more than one vehicle it is desirable to provide the remote unit with the capability of separately controlling several different base units mounted in different vehicles or in non-vehicular stations. This would avoid the necessity of carrying or obtaining a separate remote unit for each base station. It is also desirable to avoid handling the electronic key and pushing the button to activate the unit since it is sometimes inconvenient to do so. To provide a passive control which does not require the depression of a button or the like, it has been proposed to provide a system in which the mere presence of the electronic key in the immediate vicinity of the base station is sufficient to activate the base station function. In conjunction with the presence of the electronic key, it is generally preferred to require a positive act, such as pulling on the door handle, to actuate the system. A further consideration in designing such a system is the battery life of the remote unit. Since a miniature electronic key is generally desired, the battery must be small and the unit must then be very conservative of energy to operate for an extended period. In that context, a battery life of many years is desired even though the unit is used for the control of several base stations. EP-B-0077101 discloses a system in accordance with the preamble of claim 1.

The present invention seeks to provide an improved system for accessing a plurality of base stations.

A system for accessing a plurality of base stations in accordance with the present invention is characterised over EP-B-0077101 by the features specified in the characterising portion of claim 1.

In an embodiment, there is provided a system for secure entry to a plurality of base stations comprising a plurality of base units, one for each base station, for controlling a station function and at

least one remote unit coupled to the base units for communication therewith, each base unit storing a unique base number and a secure remote ID, the remote unit having a memory partitioned into assigned memory blocks one for each base unit and an additional temporary memory block, each assigned memory block containing a secure ID, the remote unit further having logic means for selectively assigning a base number to each memory block and for accessing a memory block when a corresponding base number is communicated to the remote unit to read out the secure ID from the memory block for transmission to the base unit, means for updating the ID by transmitting a new ID from the unit base to the temporary memory block, and wherein the logic means is effective when updating the ID for relating the corresponding base number to the new ID.

An embodiment of the present invention is described below, by way of illustration only, with reference to the accompanying drawings, in which:

Figure 1 is a diagram of an embodiment of system of vehicle-mounted base units and remote units;

Figure 2 is a block diagram of a base unit of the system of Figure 1;

Figure 3 is a block diagram of a remote unit of the system of Figure 1;

Figure 4 is a diagram of receiver output pulse groups with corresponding symbol identification for use by the base unit and remote unit of Figures 2 and 3;

Figure 5 is a time diagram of coded signals exchanged by the base and remote units of Figures 2 and 3;

Figure 6 is a chart of functions and signal exchanges for the base and remote units of Figures 2 and 3 for vehicle access;

Figure 7 is a chart of functions and signal exchanges for the base and remote units of Figures 2 and 3 for code updating; and

Figure 8 is a diagram of remote unit memory locations after updating.

The embodiment described in the ensuing description is directed to a system specifically designed for secure remote access to multiple vehicles via a radio link, although it should be recognized that the embodiment is equally well suited to other applications, whether vehicular, non-vehicular or mixed. In particular, the embodiment is described as a vehicle access system which is passively activated to unlock a door when the door handle is pulled or otherwise actuated.

Figure 1 shows a base station or vehicle 10 equipped with a remote access system including a base unit 12 in the vehicle and a remote unit 14X typically carried in the vehicle operator's pocket or

purse. The units are coupled by radio frequency signals effective over a short distance. As indicated by dotted lines 16 adjacent each vehicle door handle 18 and lines 20 adjacent the vehicle boot, minimum distances of only a metre or two are required although a larger radius of communication could be chosen. It is intended that when the operator carries the remote unit within range of the base unit, the system will automatically act to unlock the door without activation by the operator, provided that the identification of the remote unit can be verified. In some applications, the units are activated only when the operator touches or tries to operate the door handle 18.

The system includes base units 12' and 12" in other vehicles 10' and 10" which are similar to unit 12 and operable with the remote unit 14X so that the operator carrying the remote unit has access to each of the three vehicles. Since more than one operator may use one or more of the same vehicles, there are other remote units 14Y and 14Z which may be programmed for vehicle access.

The base unit 12 shown in Figure 2 comprises a microprocessor based controller 24, at least one unlock or other function output circuit 26, a low frequency radio transmitter 28 and antenna 30 operating at 200 kHz, and a very high frequency receiver 32 and antenna 34 operating at 300 MHz. The controller 24 stores several codes including a base number or password which is unique to the vehicle, and codes X, Y, and Z which relate to respective remote units 14X, 14Y and 14Z. Code X, which is typical, contains two components, a wakeup code and an identification code (ID) which are all specific to the remote unit 14X. The controller 24 also stores a set of function codes which are common to all the remote units 14X-Z. The function code, when transmitted, determines the operation to be performed in the remote unit, e.g., read out the ID or update the ID.

The remote unit 14X, shown in Figure 3, is similar to the other remote units 14Y, 14Z and comprises a 200 kHz receiver 36 and antenna 38 coupled thereto for receiving signals from the base unit 12. The antenna 38 is preferably a ferrite antenna capable of producing at least 3 mV signals when in the range of the base unit 12 and the receiver 36 is a comparator having its input terminals coupled across the antenna and which produces a 3 V output pulse when each 3 mV signal pulse is received.

The low frequency signal is modulated by the base unit into bursts of various lengths so that the low frequency carrier is not continuous but is segmented into bursts. The number of cycles in each burst is counted by a pulse counter 40 connected to the output of the receiver 36. The counter translates bursts of 10, 20, 30, 40, and 50 pulses into

digital symbols A, B, C, D and E, respectively. Symbols A and B comprise digital bits 0 and 1, respectively, while the symbols C, D and E comprise digital codes formed of a plurality of bits, as will become apparent below. Figure 4 depicts three bursts of pulses P having lengths of 10, 20, and 10 pulses, respectively, to indicate symbols A, B, A or bits 0, 1, 0.

The counter output is coupled to a wakeup register 42 and to a state machine 44 which comprises a logic circuit. The wakeup register 42 is also connected to the state machine 44 and may even be a part of the state machine. Both the wakeup register 42 and the state machine 44 have outputs connected to a VHF transmitter 46 operating at 300 MHz and which is coupled to an antenna 48 for transmitting signals to the base unit 12. The state machine 44 incorporates a power conservation function 45 which powers down the state machine to a low current level to deactivate most of the state machine and the transmitter 46 while the unit is "asleep", leaving just enough circuitry active to receive and process a wakeup signal. When a wakeup signal bearing the correct wakeup code is received, the rest of the system is powered up for full operation.

The state machine is also connected to a memory 50 which is partitioned into several memory blocks, here shown as four blocks including three secure memory blocks, one corresponding to each base unit, and a scratch pad or temporary memory block. When the system is initially programmed, the state machine 44 determines which memory block is assigned to which vehicle (base) and pointers are stored in the state machine 44 to identify the correct memory address for each base. Secure memory 1 is assigned to vehicle 10, secure memory 2 is assigned to vehicle 10', etc. Thus the transmitted base number ultimately determines which memory block is accessed. Each secure memory block contains the ID which is stored in the corresponding base unit or vehicle.

Optionally, each secure memory block stores auxiliary data which might be used for any of several purposes. For example, in a vehicle which has power seats or steering wheel power adjustments with position memories for each vehicle user, the auxiliary data for a given electronic key may be codes for the positions preferred by the user of that key for each vehicle used by the user. Thus the data is both personal and vehicle specific. When the ID is retrieved from the key by the base unit, the position data can be retrieved at the same time and the data would be used to position automatically the seat and/or the steering wheel. As a second example of auxiliary data, for a vehicle equipped with a keyboard and a display screen, user appointment calendar data can be entered

into the secure memory by transmission from the base unit and subsequently displayed in the same or another similarly equipped vehicle. A third example of auxiliary data applies to rental car systems. When a vehicle is parked at the rental return lot and turned off, the vehicle mileage and fuel data can be loaded into the secure memory. When the electronic key is returned to the rental office, a base unit there can read the vehicle data to be used for bill preparation.

System operation for gaining access to a vehicle is begun by the operator pulling on the door handle of, say, vehicle 10. The base unit seeks the remote units by sequentially using codes X, Y and Z to determine whether a remote unit corresponding to one of those codes is near the vehicle. Figures 5 and 6 illustrate the communication between the base unit 12 and the remote unit 14X. To initialize the remote unit, the base sends the symbol E. Then a wakeup command is sent in the form of a string of bits which includes the wakeup code (from code X), a base number, and a function code for vehicle access. The remote unit compares the wakeup code to the contents of the wakeup register. If there is agreement, the state machine 44 is fully energized. The base unit next sends a C symbol to reset the state machine and then sends a request ID signal. This comprises the code to instruct the state machine to access the indicated memory block containing ID for vehicle 10. Upon receipt of the correct instruction, the ID is released for transmission to the base unit. To effect the ID transmission, the base unit sends a series of A symbols or 0's and the state machine sends one bit of the ID for each received 0 until all the ID is transmitted. The base unit compares the received ID with the one stored in code X and unlocks the door if there is agreement. Whenever one code is compared to another, it is permissible to require less than 100% agreement to allow for communication error. When agreement is found, the signalling process ends. In the event the remote unit does not respond to the base unit signal or there is no agreement, the base unit repeats the procedure using code Y and again, if necessary, with code Z. When no match of ID's occurs, the process stops and access to the vehicle is denied. The entire procedure requires a small fraction of a second.

For improved security it is good to change the ID periodically. It is also desirable to be able to change the auxiliary data in the secure memory. These functions are initiated when the mechanical key is removed from the steering column lock. The ensuing series of events in the base and remote units is illustrated in Figure 7. Reset commands are omitted from these charts. The initialize command and wakeup code are transmitted and responded to in the same manner as in Figure 6. Then the base

unit issues a set scratchpad command and the remote unit prepares to write to the scratchpad memory block in the memory 50. Next the base unit transmits a new ID as well as new auxiliary data which are written in the scratchpad. The base unit commands that the scratchpad contents be transmitted and in response the new ID is sent. A data correction procedure is followed if errors are present. Then the old ID is requested by the base unit. The old memory block is accessed and the old ID is sent to the base unit. If the ID is verified, the state machine is commanded to move the memory block which is carried out by changing pointers in the state machine so that the address which was formerly for the scratchpad now becomes the address of the secure memory block, and the old memory block location is the new scratchpad location. This is illustrated by the memory 50 diagram of Figure 8 which may be contrasted with the memory 50 of Figure 3. If it is desired merely to update the auxiliary data without changing the ID, the same procedure is followed but the old ID is used in place of the new ID.

Claims

1. A system for accessing a plurality of base stations comprising a plurality of base units (12) each associated with a respective base station (10) and adapted to control one or more functions of its respective base station, each base unit being adapted to store therein a unique base unit number and an identification code for use in granting access to the or each function associated with its respective base station, and at least one remote unit (14) adapted to communicate with the base units (12); each remote unit comprising a memory (50) containing an identification code, processing means (44) adapted to assign a base unit number to each memory block equivalent to the base unit number of its respective base unit and, on communication of a base unit number to the remote unit, to obtain from the corresponding memory block the identification code stored therein for transmission to the base unit; characterised in that the memory (50) of each remote unit (14) is partitioned into assigned memory blocks each associated with a respective base unit (12); in that each remote unit contains a temporary memory block; and in that each base unit comprises updating means (24) adapted to update its identification code by storing a new identification code in a memory thereof and by transferring the new identification code to the temporary memory block of said remote unit, the processing means (44) being effective when updating the

identification code of a base unit to relate the corresponding base unit number to the new identification code.

2. A system according to claim 1, wherein the processing means (44) of each remote unit is adapted when updating an identification code to reassign the corresponding base unit number to the memory block thereof containing the new identification code. 5
10
3. A system according to claim 2, wherein the processing means (44) is adapted to assign the memory block formerly containing the identification code the temporary memory block. 15
4. A system according to claim 1, 2 or 3, wherein the processing means (44) is adapted to be kept in a substantially non-active state for energy conservation, each remote unit including a register (42) containing an activating code and activating means (44) operable to activate the processing means when a code matching the activating code is received by the remote unit; each base unit comprising means (24) to store the activating code or codes of the remote units and to transmit the activating code or codes to each remote unit. 20
25
30
5. A system according to any preceding claim, wherein one or more of the base stations is a vehicle and the function or functions adapted to be controlled by the respective base unit is access to the vehicle. 35

Patentansprüche

1. Ein System zum Zugreifen auf eine Vielzahl von Basisstationen mit einer Vielzahl von Basiseinheiten (12), jede zu einer respektiven Basisstation (10) gehörig und dazu angepaßt, eine oder mehrere Funktionen ihrer respektiven Basisstation zu steuern, wobei jede Basiseinheit dazu angepaßt ist, eine eindeutige Basiseinheitnummer und einen Identifikationscode zum Gebrauch im Gewähren von Zugang an die oder jede Funktion zu speichern, die zu ihrer respektiven Basisstation gehört, und zumindest einer Fernbedienungseinheit (14), die dazu angepaßt ist, mit den Basiseinheiten (12) zu kommunizieren; wobei jede Fernbedienungseinheit einen Speicher (50) umfaßt, der einen Identifikationscode, ein Verarbeitungsmittel (44), das dazu angepaßt ist, eine Basiseinheitnummer jedem Speicherblock äquivalent zu der Basiseinheitnummer ihrer respektiven Basiseinheit zuzuordnen, und auf die Übertra-

gung einer Basiseinheitnummer an die Fernbedienungseinheit aus dem entsprechenden Speicherblock den darin zum Senden an die Basiseinheit gespeicherten Identifikationscode zu erhalten; dadurch gekennzeichnet, daß der Speicher (50) von jeder Fernbedienungseinheit (14) in zugeordnete Speicherblöcke partitioniert ist, die zu einer respektiven Basiseinheit (12) gehören; dadurch, daß jede Fernbedienungseinheit einen temporären Speicherblock umfaßt; und dadurch, daß jede Basiseinheit ein Aktualisierungsmittel (24) umfaßt, das dazu angepaßt ist, ihren Identifikationscode durch Ablegen eines neuen Identifikationscodes in einem Speicher davon und durch Übertragen des neuen Identifikationscodes an den temporären Speicherblock der Fernbedienungseinheit zu aktualisieren, wobei das Verarbeitungsmittel (44) wirksam ist, wenn der Identifikationscode einer Basiseinheit aktualisiert wird, um die entsprechende Basiseinheitnummer auf den neuen Identifikationscode zu beziehen.

2. Ein System nach Anspruch 1, worin das Verarbeitungsmittel (44) von jeder Fernbedienungseinheit dazu angepaßt ist, wenn ein Identifikationscode aktualisiert wird, die entsprechende Basiseinheitnummer dem Speicherblock davon wieder zuzuordnen, der den neuen Identifikationscode umfaßt.
3. Ein System nach Anspruch 2, worin das Verarbeitungsmittel (44) dazu angepaßt ist, den Speicherblock, der vorher den Identifikationscode enthält, dem Temporärspeicherblock zuzuordnen.
4. Ein System nach Anspruch 1, 2 oder 3, worin das Verarbeitungsmittel (44) dazu angepaßt ist, in einem im wesentlichen nicht aktiven Zustand zum Energiesparen gehalten zu werden, wobei jede Fernbedienungseinheit ein Register (42) umfaßt, das einen Aktivierungscode enthält, und ein Aktivierungsmittel (44), das betätigbar ist, um das Verarbeitungsmittel zu aktivieren, wenn ein Code, der mit dem Aktivierungscode übereinstimmt, von der Fernbedienungseinheit empfangen wird; wobei jede Basiseinheit ein Mittel (24) zum Speichern des Aktivierungscode oder der -codes der Fernbedienungseinheiten umfaßt, und um den Aktivierungscode oder die -codes an jede Fernbedienungseinheit zu senden.
5. Ein System nach irgendeinem vorhergehenden Anspruch, worin eine oder mehrere der Basisstationen ein Fahrzeug ist, und die Funktion oder Funktionen, die dazu angepaßt sind,

durch die respektive Basiseinheit gesteuert zu werden, Zugang zu dem Fahrzeug ist.

vant le code d'identification au bloc mémoire temporaire.

Revendications

1. Système pour accéder à une pluralité de stations de base comprenant une pluralité de dispositifs de base (12) qui sont chacun associés à une station de base (10) respective et adaptés pour commander une ou plusieurs fonctions de leur station de base respective; chaque dispositif de base étant adapté pour stocker un numéro de dispositif de base unique et un code d'identification unique qui sert à accorder l'accès à la ou à chaque fonction associée à sa station de base respective, et au moins un dispositif distant (14) adapté pour communiquer avec les dispositifs de base (12); chaque dispositif distant comprenant une mémoire (50) contenant un code d'identification, un moyen de traitement (44) adapté pour affecter un numéro de dispositif de base à chaque bloc mémoire équivalent au numéro de dispositif de base de son dispositif de base respectif et, sur communication d'un numéro de dispositif de base au dispositif distant, pour obtenir du bloc mémoire correspondant le code d'identification stocké pour le transmettre au dispositif de base; caractérisé en ce que la mémoire (50) de chaque dispositif distant (14) est partagée en blocs mémoire affectés qui sont chacun associés à un dispositif de base associé (12); en ce que chaque dispositif distant contient un bloc mémoire temporaire; et en ce que chaque dispositif de base comprend un moyen de mise à jour (24) adapté pour mettre à jour son code d'identification en stockant un nouveau code d'identification en mémoire et en transférant le nouveau code d'identification au bloc mémoire temporaire dudit dispositif distant, le moyen de traitement (44) étant actif lorsqu'on met à jour le code d'identification d'un dispositif de base pour mettre en rapport le numéro du dispositif de base correspondant avec le nouveau code d'identification.
2. Système selon la revendication 1, dans lequel le moyen de traitement (44) de chaque dispositif distant est adapté lors de la mise à jour du code d'identification pour réaffecter le numéro du dispositif de base correspondant au bloc mémoire contenant le nouveau code d'identification.
3. Système selon la revendication 2, dans lequel le moyen de traitement (44) est adapté pour affecter le bloc mémoire qui contenait auparavant le code d'identification au bloc mémoire temporaire.
4. Système selon la revendication 1, 2 ou 3 dans lequel le moyen de traitement (44) est adapté pour être maintenu dans un état essentiellement inactif à des fins d'économie d'énergie, chaque dispositif distant comprenant un registre (42) qui contient un code d'activation et un moyen d'activation (44) pouvant fonctionner pour activer le moyen de traitement lorsqu'un code correspondant au code d'activation est reçu par le dispositif distant; chaque dispositif de base comprenant un moyen (24) pour stocker le ou les codes d'activation des dispositifs distants et pour transmettre le ou les codes d'activation à chaque dispositif distant.
5. Système selon l'une quelconque des revendications précédentes, dans lequel une ou plusieurs stations de base est un véhicule et la ou les fonctions adaptées à être commandées par le dispositif de base respectif est l'accès au véhicule.
